STANDARD OPERATION PROCEDURÉS

8-Foot Transonic Pressure Tunnel - Building 64D

Laurence & Devry

Lawrence E. Perry R.O.B., Section "E"

Ralph P. Bielat

8-Foot Tunnels Branch, FSRD

Langley 8-Foot Transonic Pressure Tunnel

The Langley 8-Foot Transonic Pressure Tunnel is located on WindTunnel Road, Building 640, in the East Area. The tunnel has certain
precautionary measures which must be observed for safe operation since
it is a closed circuit tunnel and has the capability to change the
stagnation pressure from 1/10 atm to 2.0 atms. In addition, nitrogen
gas is sometimes used whenever model tests require pressure to simulate
thrust. Certain valves must be opened or closed to purge the tunnel
circuit before personnel may be permitted to enter the test section.
New personnel shall be thoroughly indoctrinated in potentially hazardous
areas and in safe working practices before starting work. All personnel
shall report unsafe conditions to his supervisor. Suggestions for improving
safety are encouraged.

Safety Precautions

High pressure storage field. - High pressure gaseous nitrogen is available for use in the Langley 8-Foot Transonic Pressure Tunnel and 2-Foot Hypersonic Facility. The high pressure system consists of a liquid nitrogen DEWAR tank, a pumping station, a high pressure tank storage farm, and suitable high pressure distribution lines. The liquid nitrogen pumping system is designed to have safety valves located in all major elements of system to prevent over-pressurization. During nitrogen pumping operation, all personnel shall wear protective clothing and gloves to prevent liquid nitrogen from coming in contact with skin. A protective booth is also located at the pumping station where safety equipment is also stored.

Tunnel stagnation pressure control. The stagnation pressure in the Langley 8-foot transonic pressure tunnel can be varied from 1/10-atm. to 2.0 atms. The stagnation pressure is controlled with the use of a 10,000 c.f.m. compressor which is used to vary the pressure from 1/4-atm. to 2.0 atms. and with the use of a 100,000 c.f.m. compressor in series with the 10,000 c.f.m. compressor when stagnation pressures less than 1/4-atm are desired. Safety valves are conveniently located in the tunnel circuit to prevent over-pressurization above 2.0 atms. The 10,000 c.f.m. compressor which is used to reduce the tunnel stagnation pressure to 1/4-atm. has guide vanes which will automatically close at 450 p.s.f. thus making the compressor inoperable.

Precautionary measures to observe when securing tunnel prior to run.—

Before tunnel doors and hatches are closed, all working tools, mats,

portable lights, and the like shall be removed from the test section. A

check shall be made to determine that all personnel are out of the tunnel

circuit before the external doors of the pressure vessel are closed and

secured with a lock. In the event that personnel were locked inadvertently

in the test chamber, an alarm bell located in the control room of the

tunnel can be activated with an emergency switch which is located in the

test chamber. The emergency switch is also locked in with the 10,000

c.f.m. compressor and activation of this switch will shut-down the

compressor.

<u>Precautionary measures to observe before entering tunnel.</u> - Before entry can be made to the tunnel, the tunnel stagnation pressure must

be brought to atmospheric pressure. Before work is to be done on the model, mats are to be placed in the tunnel to prevent personnel from stepping through slots which are located in the tunnel floor.

Other Precautions. - (1) All floor access hatches located on second and third floors shall have barricades errected when open to prevent personnel from falling through. (2) Chain barricades shall be in place when lowering or raising test section elevator. (3) Before starting tunnel, a check sheet with 91 items to be checked off shall be filled out, checked, and signed by shift leader. (Check sheet enclosed)

Safe Shop Practices

Refer to NASA safety pamphlets with regard to use of band saws, drill presses, grinding wheels, lathers, etc. However, a few reminders are in order in safe shop practices.

Safe shop practices. - (a) Only authorized personnel shall use acetylene welding equipment. No oil shall be used on any oxygen fittings or connection. (b) Safety glasses shall be worn during all sawing, drilling, grinding, chipping, filing, etc. Safety glasses are available in areas where danger from flying objects exist. (c) Observe warning signs indicating dangerous materials or areas. (d) Chisels which have become mushroomed shall be ground smooth before use. (e) All electrical tools shall be properly grounded before use. (f) Make sure all protective guards are in proper place on machinery and tools. (g) Clean chips from surface with brush instead of hands. (h) Keep floor and equipment clean around rotating machinery.

Red "Hold Off" Tags

Whenever the possibility of harm to machinery or injury to workmen exists, red tags shall be used to hold-off rotating machinery, electrical switches, pressure valves, and other control devices.
